Adopted
1967
Revised
Reaffirmed
1972, 1977

Purpose
The American Academy of Pediatric Dentistry (AAPD) intends this guideline to help practitioners and parents make decisions concerning appropriate use of fluoride as part of the comprehensive oral health care for infants, children, adolescents, and persons with special health care needs.

Methods
A thorough review of the scientific literature pertaining to the use of systemic and topical fluoride was completed to revise and update this guideline. A MEDLINE search was conducted using the terms “fluoride”, “fluoridation”, “acidulated phosphate fluoride”, “fluoride varnish”, “fluoride therapy”, and “topical fluoride”. Expert opinions and best current practices also were relied upon for this guideline.

Background
Use of fluorides for the prevention and control of caries is documented to be both safe and highly effective.1-5 Fluoride has several caries-protective mechanisms of action, including enamel remineralization and altering bacterial metabolism to help prevent caries.6 Optimizing fluoride levels in water supplies is an ideal public health measure because it is effective and inexpensive and does not require conscious daily cooperation from individuals.4,7-10 Daily fluoride exposure through water supplies and monitored use of fluoride toothpaste can be effective preventive procedures. Determination of dietary sources of fluoride before prescribing supplements can help reduce intake of excess fluoride.11-13 Sources of dietary fluoride may include drinking water from home, day care, and school; beverages such as soda12, juice15, and infant formula11,16,17; prepared food18; and toothpaste. Infant formulas (powdered or liquid) and water bottled specifically for infants have varying concentrations of fluoride.16-24 Fluorosis has been associated with cumulative fluoride intake during enamel development, with the severity dependent on the dose, duration, and timing of intake.4

Professionally-applied topical fluoride treatments are efficacious in reducing caries in children with moderate or high caries risk.5,7,8,25-32 Two percent sodium fluoride (NaF; 0.9% F; 9000 ppm F)1, 1.23% acidulated phosphate fluoride (APF; 1.23% F; 12,300 ppm F) solution or gel33-44, and 5% sodium fluoride varnish (NaFV; 2.26% F; 22,500 ppm F)1,41,43,45-54 are the most commonly used agents for professionally-applied fluoride treatments.1,45 Some topical fluoride products are marketed with recommended treatment times of less than 4 minutes, but the majority of studies suggest that 4-minute applications are more efficacious.1,8,36,57,58 Children at higher caries risk may require additional or more frequent fluoride therapies.7,59,60 If an individual’s caries risk level is uncertain, treating this person as high risk is prudent until further experience allows a more accurate assessment.4

Recommendations
Systemically-administered fluoride supplements
Fluoride supplements should be considered for all children drinking fluoride-deficient (<0.6 ppm F) water. After determining the fluoride level of the water supply or supplies (either through contacting public health officials or water analysis), evaluating other dietary sources of fluoride, and assessing the child’s caries risk, the daily fluoride supplement dosage can be determined using the Dietary Fluoride Supplementation Schedule (Table 1). To optimize the topical benefits of systemic fluoride supplements, the child should be encouraged to chew or suck fluoride tablets.1

Professionally-applied topical fluoride treatment
Professional topical fluoride treatments should be based on caries-risk assessment.1,4,5,7,60 A pumice prophylaxis is not an essential prerequisite to this treatment.61 Appropriate precautionary measures should be taken to prevent swallowing of any professionally-applied topical fluoride. Children at moderate caries risk should receive a professional fluoride treatment at least every 6 months; those with high caries risk should receive greater frequency of professional fluoride applications (ie, every 3-6 months).7,32,59,62-67 Ideally, this would occur as
part of a comprehensive preventive program in a dental home.\textsuperscript{68} When a dental home cannot be established for individuals with increased caries risk as determined by caries risk assessment, periodic applications of fluoride varnish by trained non-dental healthcare professionals may be effective in reducing the incidence of early childhood caries.\textsuperscript{50-54,69,70}

**Fluoride-containing products for home use**

Therapeutic use of fluoride for children should focus on regimens that maximize topical contact, preferably in lower-dose, higher-frequency approaches.\textsuperscript{1} Fluoridated toothpaste (generally 0.1% F; 1,000 ppm F) should be used twice daily as a primary preventive procedure.\textsuperscript{1,71} Twice daily use has benefits greater than once daily brushing.\textsuperscript{1} Parents should be counseled on their child’s caries risk, dispensing an appropriate volume of toothpaste onto a soft, age-appropriate sized toothbrush, frequency of brushing, and performing/assisting brushing of young children. A ‘smear’ of fluoridated toothpaste (see Figure 1) for children less than 2 years of age may decrease risk of fluorosis.\textsuperscript{72} A ‘pea-size’ amount (see Figure 1) of toothpaste is appropriate for children aged 2 through 5 years.\textsuperscript{72,74} To maximize the beneficial effect of fluoride in the toothpaste, rinsing after brushing should be kept to a minimum or eliminated altogether.\textsuperscript{72,75}

Additional at-home topical fluoride regimens utilizing increased concentrations of fluoride should be considered for children at high risk for caries.\textsuperscript{1,4,7,60} These may include over-the-counter (0.02% F; 200 ppm F) or prescription strength (0.09% F; 900 ppm F) formulations. Brush-on fluoride gels (0.5% F; 5,000 ppm F) may be incorporated into a caries-prevention program for a school-aged child at high risk.
