Policy on dental bleaching for child and adolescent patients

Originating Council
Council on Clinical Affairs

Adopted
2004

Purpose
The American Academy of Pediatric Dentistry (AAPD) recognizes that the desire for dental whitening in pediatric and adolescent patients has increased. This policy is intended to help professionals and patients make informed decisions about the indications, efficacy, and safety of bleaching primary and young permanent teeth and incorporate such care into a comprehensive treatment plan.

Methods
This policy is based on a review of the current dental and medical literature related to the dental bleaching. A MEDLINE search was conducted using the terms “dental bleaching”, “dental whitening”, and “tooth bleaching.” Expert opinions and best current practices also were relied upon for this policy.

Background/Literature review
Through news stories and advertisements, the public has become more aware of advances in cosmetic dentistry. Both the variety and availability of bleaching products on the market have increased. Consequently, parents and the news media request information on dental whitening for children and adolescents with increasing frequency.

Clinical indications for dental whitening for individual teeth may include discoloration resulting from a traumatic injury (ie, calcific metamorphosis, darkening with devitalization); irregularities in enamel coloration of a permanent tooth due to trauma or infection of the related primary tooth; or intrinsic discoloration/staining (eg, fluorosis, tetracycline staining). A negative self-image due to a discolored tooth or teeth can have serious consequences on adolescents and could be considered an appropriate indication for bleaching. Due to the difference in the thickness of enamel of primary and permanent teeth, tooth coloration within a dental arch may vary significantly during the mixed dentition. However, full arch cosmetic bleaching during this developmental stage would result in mismatched dental appearance once the child is in the permanent dentition.

Dental whitening may be accomplished by using either professional or at-home bleaching modalities. Advantages of in-office whitening include:

1. An initial professional examination to help identify causes of discoloration and clinical concerns with treatment (eg, existing restorations, side effects)
2. Professional control, including use of acceleratants (eg, lights, lasers) and soft-tissue protection
3. Patient compliance
4. Rapid results
5. Stability of results

The pre-treatment professional assessment allows identification of pulp pathology that may be associated with a single discolored tooth. This examination also identifies restorations that are faulty or would not be affected by the bleaching process, and the associated costs for replacing such restorations to maximize esthetic results.\(^\text{1,4,6,10-13}\) By using photographs and/or a shade guide, the dentist can document the effectiveness of treatment. As well as providing in-office bleaching procedures, a dentist may fabricate custom trays for at-home use of a bleaching product. Custom trays ensure intimate fit and greater efficiency of bleaching agents. Over-the-counter products for at-home use include bleaching gels, whitening strips, and brush-on agents. Their main advantages include patient convenience and lower associated costs.

Peroxide-containing whiteners or bleaching agents improve the appearance by changing the intrinsic color of the tooth. The professional-use products usually range from 10 percent carbamide peroxide (equivalent to about 3 percent hydrogen peroxide) to 38 percent carbamide peroxide. Carbamide peroxide is the most commonly used active ingredient in dentist-dispensed home-use tooth bleaching products.\(^\text{10}\) These agents sometimes are used sequentially. In-office bleaching products require isolation with a rubber dam or a protective gel to shield the gingival soft tissues. Home-use bleaching products contain lower concentrations of hydrogen peroxide or carbamide peroxide.\(^\text{1-3,14-16}\) Many whitening toothpastes contain polishing or chemical agents to improve tooth appearance by removing surface stains through gentle polishing, chemically chelating, or other non-bleaching action.\(^\text{10}\)

Side effects from bleaching vital and nonvital teeth have been documented. It should be noted that most of the research on bleaching has been performed on adult patients with only a small amount of published bleaching research using child or adolescent patients.\(^\text{1-3,14-16}\) The more common side effects associated with bleaching vital teeth are tooth sensitivity and tissue irritation. Sensitivity affects 8-66% of patients and often occurs during the early stages of treatment.\(^\text{4,9,11,17-21}\) Tissue irritation, in most cases, results from an ill-fitting tray rather than the bleaching agents and no longer occurs once a more accurately fitted tray is used. Both sensitivity and tissue irritation usually are temporary and cease with the discontinuance of treatment.\(^\text{4,11,22}\) Another side effect associated with bleaching vital teeth is increased marginal leakage of an existing restoration.\(^\text{4,11,22}\) The more common side effects from internal bleaching of nonvital teeth are external root resorption\(^\text{12,23-26}\) and ankylosis. With external bleaching of non-vital teeth, the most common side effect is increased marginal leakage of an existing restoration.\(^\text{26-30}\) One of the degradation by-products of hydrogen peroxide or carbamide peroxide results in a hydroxyl free radical. This byproduct has been associated with periodontal tissue damage and root resorption. Due to the concern of the hydroxyl free radical\(^\text{31-36}\) and the potential side effects of dental bleaching, minimizing exposure at the lowest effective concentration of hydrogen peroxide or carbamide peroxide is recommended.

Current literature and clinical studies support the use of sodium perborate mixed with water for bleaching nonvital teeth.\(^\text{13,37}\) In the past, sodium perborate has been mixed with hydrogen peroxide for this technique. Studies have shown higher incidences of root resorption when mixed with hydrogen peroxide.\(^\text{12,38-41}\) In addition to the
discontinued use of hydrogen peroxide, there is also discontinued use of heating any
mixture of sodium perborate.\textsuperscript{42}

\section*{Policy Statement}

The AAPD encourages
1. the judicious use of bleaching for vital and nonvital teeth.
2. patients to consult their dentists to determine appropriate methods for and timing
   of dental whitening within the context of an individualized, comprehensive, and
   sequenced treatment plan.
3. dental professionals and consumers to consider side effects when contemplating
   dental bleaching for child and adolescent patients.
4. further research of dental whitening agents in children.

The AAPD discourages full-arch cosmetic bleaching for patients in the mixed dentition.
