Best Practices on Periodicity of Examination, Preventive Dental Services, Anticipatory Guidance/Counseling, and Oral Treatment for Infants, Children, and Adolescents

Review Council
Council on Clinical Affairs
Revised
2013-2018

Purpose
The American Academy of Pediatric Dentistry (AAPD) intends these recommendations to help practitioners make clinical decisions concerning preventive oral health interventions, including anticipatory guidance and preventive counseling, for infants, children, and adolescents.

Methods
This guideline was originally developed by the Clinical Affairs Committee and adopted in 1991. This document is a revision of the previous version, last revised in 2009-2013. The update used electronic database and hand searches of articles in the medical and dental literature using the terms: periodicity of dental examinations, dental recall intervals, preventive dental services, anticipatory guidance and dentistry, caries risk assessment, early childhood caries, dental caries prediction, dental care cost effectiveness and children, periodontal disease and children and adolescents U.S., pit and fissure sealants, dental sealants, fluoride supplementation and topical fluoride, dental trauma, dental fracture and tooth, non-nutritive oral habits, treatment of developing malocclusion, removal of wisdom teeth, removal of third molars; fields: all; limits: within the last 10 years, humans, English, and clinical trials; birth through age 18. From this search, 3,418 1,884 articles matched these criteria and were evaluated by title and/or abstract. Information from 11349 articles was chosen for review to update this document. When data did not appear sufficient or were inconclusive, recommendations were based upon expert and/or consensus opinion by experienced researchers and clinicians.

Background
Professional dental care is necessary to maintain oral health1 (US DHHS 2000). The AAPD emphasizes the importance of initiating professional oral health intervention in infancy and continuing through adolescence and beyond2 (US DHHS 2000, US DHHS 2003, Lewis and Ismail 1995). The periodicity of professional oral health intervention and services is based on a patient’s individual needs and risk indicators3,4,5,6,7,8. Each age group, as well as each individual child, has distinct developmental needs to be addressed at specific intervals as part of a comprehensive evaluation2,9-11. Continuity of care is based on the assessed needs of the individual patient and assures appropriate management of all oral conditions, dental disease, and injuries12-18. The early dental visit to establish a dental home provides a foundation upon which a lifetime of preventive education and oral health care can be built. The early establishment of a dental home has the potential to provide more effective and less costly dental care when compared to dental care provided in emergency care facilities or hospitals19,23. Anticipatory guidance and counseling are essential components of the dental visit2,9,10,19,20,22,24-27 (CDC 2004). Collaborative efforts and effective communication between medical and dental homes is essential to prevent oral disease and promote oral and overall health among children. Medical professionals can play an important role in children’s oral health by providing primary prevention and coordinated care. Equally, dentists can improve the overall health of children not only by treating dental disease, but also by proactively recognizing child abuse, preventing traumatic injuries through anticipatory guidance, preventing obesity by longitudinal dietary counseling, and monitoring of weight status28. In addition, dentists can have an important role in assessing immunization status and developmental milestones for potential delays, as well as making appropriate referral for further neurodevelopmental evaluations and therapeutic services29. The unique opportunity dentists have to help address overall health issues strengthens as children get older since annual well child visits decreases while dental recall visits increase. Research shows that children aged 6- to 12-years are, on average, four times more likely to visit a dentist than a pediatrician30,31.

Recommendations

This guideline document addresses periodicity and general principles of examination, preventive dental services, anticipatory guidance/counseling, and oral treatment for children who have no contributory medical conditions and are developing normally. An accurate, comprehensive, and up-to-date medical, dental, and social histories are necessary for correct diagnosis and effective treatment planning. Recommendations may be modified to meet the unique requirements of patients with special health care needs32.

CCA 1h. BP_Periodicity
Clinical oral examination

The first examination is recommended at the time of the eruption of the first tooth and no later than 12 months of age. The developing dentition and occlusion should be monitored throughout eruption at regular clinical examinations. Evidenced-based prevention and early early detection and management of caries/oral conditions can improve a child’s oral/general health, general health and, well-being, and school readiness. It has been reported that the number and cost of dental procedures among high-risk children is less for those seen at an earlier age versus later, confirming the fact that the sooner a child is seen by a dentist, the less treatment needs they are likely to have in the future. On the other hand, delayed diagnosis of dental disease can result in exacerbated problems which lead to more extensive and costly care. Early diagnosis of developing malocclusions may allow for timely therapeutic intervention.

Components of a comprehensive oral examination include assessment of:

- General health/growth assessment.
- Pain.
- Extraoral soft tissue.
- Temporomandibular joint.
- Intraoral soft tissue.
- Oral hygiene and periodontal health.
- Intraoral hard tissue.
- Developing occlusion
- Caries risk.
- Behavior of child.

Based upon the visual examination, the dentist may employ additional diagnostic aids (e.g., radiographs, photographs, pulp vitality testing, laboratory tests, study casts).

The most common interval of examination is six months should be based on the child’s individual needs or risk status/susceptibility to disease however, some patients may require examination and preventive services at more or less frequent intervals, based upon historical, clinical, and radiographic findings (ADA — The Use of Dental Radiographs: Update and Recommendations 2006, Greenwell 2001).

Caries and its sequelae are among the most prevalent health problems facing infants, children, and
adolescents in America49 (US DHHS 2000). Carious Caries lesions are cumulative and progressive and, in
the primary dentition, are highly predictive of caries occurring in the permanent dentition6,50 (Li and
Wang 2002, Powell 1998). Reevaluation and reinforcement of preventive activities contribute to
improved instruction for the caregiver of the child or adolescent, continuity of evaluation of the patient’s
health status, and repetitive exposure to dental procedures, potentially allaying anxiety and fear for the
apprehensive child or adolescent51. Individuals with special health care needs may require individualized
preventive and treatment strategies that take into consideration the unique needs and disabilities of the
patient32.

Caries-risk assessment
Risk assessment is a key element of contemporary preventive care for infants, children, adolescents, and
persons with special health care needs. It should be carried out as soon as the first primary teeth erupt and
reassessed periodically by dental and medical providers6,25. Its goal is to prevent disease by (1) identifying
and minimizing causative factors (e.g., microbial burden, dietary habits, plaque accumulation) and
optimizing protective factors (e.g., fluoride exposure, oral hygiene, sealants) children at high risk for
caries, (2) developing individualized preventive measures and caries management, as well as (3) aiding
the practitioner in determining appropriate periodicity of services25,52,53. Taking into consideration that the
etiology of dental caries is multifactorial and complex, current caries-risk assessment models entail a
combination of factors including diet, fluoride exposure, host susceptibility, and microflora analysis and
consideration of how these factors interact with social, cultural, and behavioral factors. More
comprehensive models that include social, political, psychological, and environmental determinants of
health are also available54-57. Caries risk assessment forms and caries management protocols are available
and aimed to simplify and clarify the process25,58,59 (CDC 2001). Sufficient evidence demonstrates certain
groups of children at greater risk for development of early childhood caries (ECC) would benefit from
infant oral health care24,33,60-64. Infants and young children have unique caries-risk factors such as ongoing
establishment of oral flora and host defense systems, susceptibility of newly erupted teeth, and
development of dietary habits. Because the etiology of ECC is multifactorial and significantly influenced
by health behaviors65, preventive messages for expectant parents and parents of very young children
should target risk factors (e.g., early mutans streptococci contamination, poor oral hygiene habits,
nighttime feeding, high sugar consumption frequency) known to place children at a higher risk for
developing caries24,33,57,66. Children are most likely to develop caries if mutans streptococci are acquired at
an early age (Harris et al 2004, Berkowitz 2006). The characteristics of ECC and the availability of
CCA 1h. BP_Periodicity
which is nearly universal in children and adolescents, it usually responds to thorough removal of bacterial deposits and improved oral hygiene[47,79,80]. Hormonal fluctuations, including those occurring during the onset of puberty and adolescent pregnancy, can modify the gingival inflammatory response to dental plaque[47,48,81]. Children can develop any of the several forms of periodontitis, with aggressive periodontitis occurring more commonly in children and adolescents than adults[47,48,80].

Caries risk may change quickly during active dental eruption phases. Newly erupted teeth may be at higher risk of developing caries, especially during the post-eruption maturation process. Children who exhibit higher risk of developing caries and/or periodontal disease would benefit from recall appointments at greater frequency (e.g., every three months) than every six months[3,4,8,10,11,25,59]. This allows increased professional fluoride therapy application and improvement of oral health by demonstrating proper oral hygiene techniques, in addition to microbial monitoring, antimicrobial therapy reapplication, and reevaluation of behavioral changes for effectiveness[3,10,48,59,82-84].

Fluoride contributes to the prevention, inhibition, and reversal of caries[85-87] (CDC 2004). Professional topical fluoride treatments should be based on caries risk assessment and be part of a comprehensive preventive program in a dental home[10,25,86,89] (CDC 2001, Facts about Fluoride 2006, ADA Fluoride 2006). Plaque and pellicle are not a barrier to fluoride uptake in enamel[10] (Johnston and Lewis 1995, Ripa 1984, Bader, Shugars and Bonito 2001). Consequently, there is no evidence of a difference in caries rates or fluoride uptake in patients who receive rubber cup prophylaxis or a toothbrush prophylaxis before fluoride treatment[88,89] (Johnston and Lewis 1995, Ripa 1984). Precautionary measures should be taken to prevent swallowing of any professionally applied topical fluoride. Children at moderate caries risk should receive a professional fluoride treatment at least every six months; those with high caries risk should receive greater frequency of professional fluoride applications (e.g., every three to six months)[85,88-92] (Bader, Shugars and Bonito 2001).

**Fluoride supplementation**

Fluoride contributes to the prevention, inhibition, and reversal of caries (Adair 2006, AAPD Guideline-Fluoride Therapy, CDC 2001, Tinanoff 2009). The AAPD encourages optimal fluoride exposure for every child, recognizing fluoride in the community water supplies as the most beneficial and cost-effective preventive intervention. Fluoride supplementation should be considered for children at moderate...
to high caries risk when fluoride exposure is not optimal. Determination of dietary fluoride sources (e.g., drinking water, toothpaste, foods, beverages) before prescribing supplements is required and can help reduce intake of excess fluoride. In addition, supplementation should be in accordance with the guidelines recommended by the AAPD.

Radiographic assessment

Radiographs are a valuable adjunct in the oral health care of infants, children, and adolescents used to diagnose and monitor oral diseases, evaluate dentoalveolar trauma, as well as monitor dentofacial development and the progress of therapy. Timing of initial radiographic examination should not be based on the patient’s age, but upon each child’s individual circumstances. The need for dental radiographs can be determined only after consideration of the patient’s medical and dental histories, completion of a thorough clinical examination, and assessment of the patient’s vulnerability to environmental factors that affect oral health. Every effort must be made to minimize the patient’s exposure by applying good radiological practices (e.g., use of protective aprons and thyroid collars, when appropriate) and by following the ALARA Principle (As Low as Reasonably Achievable).

Anticipatory guidance/counseling

Anticipatory guidance is the process of providing practical, developmentally-appropriate information about children’s health to prepare parents for the significant physical, emotional, and psychological milestones. Individualized discussion and counseling should be an integral part of each visit. Topics to be included are oral/dental development, growth and speech/language development, nonnutritive habits, diet and nutrition, injury prevention, development, tobacco use, substance use/abuse, intraoral/perioral piercing and oral jewelry/accessories.

Anticipatory guidance regarding the characteristics of a normal healthy oral cavity should occur during infant oral health visits and throughout follow-up dental visits. This allows parents to measure against any changes such as, but not limited to, growth delays, traumatic injuries, and presence of poor oral hygiene or caries. Tooth development and chronology of eruption can help parents better understand the implications of delayed or accelerated tooth emergence, the role of fluorides in newly erupted teeth that may be at higher risk of developing caries, especially during the post-eruption maturation process. Assessment of developmental milestones (i.e., fine/gross motor skills, language, social interactions) is crucial for early recognition of potential delays and appropriate referral to therapeutic services. Speech
and language are integral components of a child’s early development\(^{101}\). Deficiencies and abnormal delays in speech and language production can be recognized early and referral made to address these concerns. Communication and coordination of appliance therapy with a speech and language professional can assist in the timely treatment of speech disorders\(^{101}\).

Oral habits (e.g., nonnutritive sucking - digital and pacifier habits, bruxism, tongue thrust swallow and abnormal tongue position, abnormal tongue thrusts, self-injurious/self-mutilating behavior) may apply forces to teeth and dentoalveolar structures. Although early use of pacifiers and digit sucking are considered normal, habits of sufficient frequency, intensity, and duration can contribute to deleterious changes in occlusion and facial development\(^{27}\). It is important to discuss the need for early pacifier and digit sucking, then the need to wean from the habits before malocclusion or skeletal dysplasias occur\(^{27}\). Early dental visits provide an opportunity to encourage parents to help their children stop sucking habits by age three years or younger. For school-aged children and adolescent patients, counseling regarding any existing habits (e.g., fingernail biting, clenching, bruxism) is appropriate\(^{27}\). Parents should be provided with information regarding the potential immediate and long-term effects on the craniofacial complex and dentition from a habit. If treatment is indicated, habit treatment include patient/parent counseling, behavior modification techniques, appliance therapy, or referral to other providers including, but not limited to, orthodontists, psychologists, or otolaryngologists\(^{27}\).

Oral hygiene counseling involves the parent and patient. Initially, oral hygiene is the responsibility of the parent. As the child develops, home care is performed jointly by parent and child. When a child demonstrates the understanding and ability to perform personal hygiene techniques, the health care professional should counsel the child. The effectiveness of home care should be monitored at every visit and includes a discussion on the consistency of daily oral hygiene preventive activities, including adequate fluoride exposure\(^{3,4,9,25,85,103}\).

Caries-conducive dietary practices. The development of dietary habits and childhood food preferences appear to be established early and may affect the oral health as well as general and well-being of a child\(^{104}\), probably by 12 months of age, and are maintained throughout early childhood (Douglass 2000, Reisine and Douglass 1998). The establishment of a dental home no later than 12 months of age allows dietary and nutrition counseling to occur early. This helps parents to develop proper oral health habits early in their child’s life, rather than trying to change established unhealthy habits later. During infancy,
counseling should focus on breastfeeding, bottle or no-spill cup usage, concerns with nighttime feedings, frequency of in-between meal consumption of sugar-sweetened beverages (e.g., sweetened milk, 100 percent juice, soft drinks, fruit drinks, sports drinks) and snacks, as well as special diets. Dietary practices, including prolonged and/or frequent bottle or training cup with sugar-containing drinks and frequent between-meal consumption of sugar-containing snacks or drinks (e.g., juice, formula, soda), increase the risk of caries (Reisine and Douglass 1998, Tinanoff and Palmer 2000). The role of carbohydrates in caries initiation is unequivocal. Acids in carbonated beverages and sports drinks can have a deleterious effect (i.e., erosion) on enamel (Li, Zou and Dig 2012, Jawale et al 2012, Gambon et al 2011). Excess consumption of carbohydrates, fats, and sodium contribute to poor systemic health. Dietary analysis and the role of dietary choices on oral health, malnutrition, and obesity should be addressed through nutritional and preventive oral health counseling at periodic visits. The U.S. Department of Health and Human Services and the U.S. Department of Agriculture Food Plate (USDA) and Center for Disease Control and Prevention/National Center for Health Statistics’ Growth Charts (CDC Growth Charts) provide dietary guidelines every five years to help Americans two years of age and older make healthy choices to help prevent chronic diseases and promote a healthy diet guidance for parents and their children and promote better understanding of the relationship between healthy diet and development.

Traumatic dental injuries that occur in preschool, school-age children, and young adults comprise 5 percent of all injuries for which treatment is sought. Facial trauma that results in fractured, displaced, or lost teeth can have significant negative functional, esthetic, and psychological effects on children (Cortes, Marcenes and Shelham 2002). Practitioners should provide age-appropriate injury prevention counseling for oro-facial trauma. Initially, discussions would include advice regarding play objects, pacifiers, car seats, and electrical cords. As motor coordination develops and the child grows older, the parent/patient should be counseled on additional safety and preventive measures, including use of athletic mouthguards for sporting activities. The greatest incidence of trauma to the primary dentition occurs at two to three years of age, a time of increased mobility and developing coordination (Flores 2002). The most common injuries to permanent teeth occur secondary to falls, followed by traffic accidents, violence, and sports (Rocha and Cardoso 2001, Caldas and Burgos 2001, Skaare and Jacobsen 2003, Tapias et al 2003). Dental injuries could have improved outcomes not only if the public were aware of first-aid measures and the need to seek immediate treatment, but also if the injured child had access to emergency care at all times. Concerns with caregivers’ dissatisfaction with experienced barriers to access.
care, specifically the referral out of the dental home for emergency dental care, have been reported\textsuperscript{112}. Therefore, it is important that all primary care providers inform parents about ways to access emergency care for dental injuries and provide telephone numbers to access a dentist, including for after-hours emergency care\textsuperscript{113}.

Nonnutritive oral habits (e.g., digital and pacifier habits, bruxism, abnormal tongue thrusts) may apply forces to teeth and dentoalveolar structures (AAPD Guideline-Developing Dentition). Although early use of pacifiers and digit sucking are considered normal, habits of sufficient frequency, intensity, and duration can contribute to deleterious changes in occlusion and facial development (AAPD Guideline-Developing Dentition). It is important to discuss the need for early pacifier and digit sucking, then the need to wean from the habits before malocclusion or skeletal dysplasias occur (AAPD Guideline-Developing Dentition). Early dental visits provide an opportunity to encourage parents to help their children stop sucking habits by age three years or younger. For school-aged children and adolescent patients, counseling regarding any existing habits (e.g., fingernail biting, clenching, bruxism) is appropriate (AAPD Guideline-Developing Dentition).

Speech and language are integral components of a child’s early development (American Speech-Language-Hearing Association). Deficiencies and abnormal delays in speech and language production can be recognized early and referral made to address these concerns. Communication and coordination of appliance therapy with a speech and language professional can assist in the timely treatment of speech disorders (American Speech-Language-Hearing Association).

Smoking and smokeless tobacco use almost always are initiated and established in adolescence\textsuperscript{114-116} (CDC 1994). During this time period, children may be exposed to opportunities to experiment with other substances that negatively impact their health and well-being. The most common tobacco products include cigarettes, cigars, hookahs, snus, smokeless tobacco, pipes, bidis and kretteks (unfiltered cigarettes from India), dissolvable tobacco, and electronic cigarettes. In 2016, 7.2 percent of middle school students and 20.2 percent of high school students reported current tobacco product use\textsuperscript{117}. E-cigarette use rose from 1.5 percent to 16.0 percent among high school students and from 0.6 percent to 5.3 percent among middle school students from 2011 to 2015\textsuperscript{117}. Practitioners should provide education regarding the serious health consequences of tobacco use and exposure to second hand smoke\textsuperscript{97,117} (CDC 1994). The practitioner may need to obtain information regarding tobacco use and alcohol/drug abuse confidentially from an adolescent patient\textsuperscript{9,100}. When tobacco or substance abuse has been identified, practitioners should
provide brief interventions for encouragement, support, and positive reinforcement for avoiding substance use\textsuperscript{97,100} referral for appropriate intervention is indicated. If indicated, dental practitioners should provide referrals to primary care providers or behavioral-health/addiction specialists for assessment and/or treatment of substance use disorders in adolescents\textsuperscript{100}.

Complications from intraoral/perioral piercings can range from pain, infection, and tooth fracture to life-threatening conditions of bleeding, edema, and airway obstruction\textsuperscript{99}. Although piercings most commonly are observed in the teenaged pediatric dental patient, education regarding pathologic conditions and sequelae associated with these piercings should be initiated for the preteen child/parent and reinforced during subsequent periodic visits (AAPD Policy-Intraoral/Perioral Piercing). The AAPD strongly opposes the practice of piercing intraoral and perioral tissues and use of jewelry on intraoral and perioral tissues due to the potential for pathological conditions and sequelae associated with these practices\textsuperscript{99}.

**Radiographic assessment**

Appropriate radiographs are a valuable adjunct in the oral health care of infants, children, and adolescents (AAPD Guideline-Radiographs, ADA—The Use of Dental Radiographs; Update and Recommendations 2006). Timing of initial radiographic examination should not be based on the patient’s age (ADA—The Use of Dental Radiographs; Update and Recommendations 2006). Rather, after review of an individual’s history and clinical findings, judicious determination of radiographic needs and examination can optimize patient care while minimizing radiation exposure (AAPD Guideline-Radiographs, ADA—The Use of Dental Radiographs; Update and Recommendations 2006). The U.S. Food and Drug Administration/ADA guidelines were developed to assist the dentist in deciding under what circumstances specific radiographs are indicated (ADA—The Use of Dental Radiographs; Update and Recommendations 2006).

**Treatment of dental disease/injury**

Health care providers who diagnose oral disease or trauma should either provide therapy or refer the patient to an appropriately trained individual for treatment\textsuperscript{118}. Immediate intervention is necessary to prevent further dental destruction, as well as more widespread health problems. Postponed treatment can result in exacerbated problems that may lead to the need for more extensive care\textsuperscript{22,34,35,40}. Early intervention could result in savings of health care dollars for individuals, community health care programs, and third-party payors\textsuperscript{22,34,35,37,40}.
Treatment of developing malocclusion

Guidance of eruption and development of the primary, mixed, and permanent dentitions is an integral component of comprehensive oral health care for all pediatric dental patients. Dentists have the responsibility to recognize, diagnose, and manage or refer abnormalities in the developing dentition as dictated by the complexity of the problem and the individual clinician’s training, knowledge, and experience. Early diagnosis and successful treatment of developing malocclusions can have both short-term and long-term benefits, while achieving the goals of occlusal harmony and function and dentofacial esthetics. Early treatment is beneficial for many patients, but is not indicated for every patient. When there is a reasonable indication that an oral habit will result in unfavorable sequelae in the developing permanent dentition, any treatment must be appropriate for the child’s development, comprehension, and ability to cooperate. Use of an appliance is indicated only when the child wants to stop the habit and would benefit from a reminder. At each stage of occlusal development, the objectives of intervention/treatment include: (1) reversing adverse growth, (2) preventing dental and skeletal disharmonies, (3) improving esthetics of the smile, (4) improving self-image, and (5) improving the occlusion.

Sealants

A 2016 systematic review concluded sealants are effective in preventing and arresting pit-and-fissure occlusal caries lesions of primary and permanent molars in children and adolescents and can minimize the progression of noncavitated occlusal caries lesions. Sealants reduce the risk of pit and fissure caries in susceptible teeth and are cost-effective when maintained. They are indicated for primary and permanent teeth with pits and fissures that are predisposed to plaque retention. At-risk pits and fissures should be sealed as soon as possible. Because caries risk may increase at any time during a patient’s life due to changes in habits (e.g., dietary, home care), oral microflora, or physical condition, unsealed teeth subsequently might benefit from sealant application. The need for sealant placement should be reassessed at periodic preventive care appointments. Sealants should be monitored and repaired or replaced as needed.

Third molars

Panoramic or periapical radiographic assessment is indicated during late adolescence to assess the presence, position, and development of third molars.
A decision to remove or retain third molars should be made before the middle of the third decade. Impacted third molars are potentially pathologic. Pathologic conditions generally are more common with an increase in age. Evaluation and treatment may require removal, exposure, and/or repositioning. In selected cases, long-term clinical and radiographic monitoring may be needed. Treatment should be provided before pathologic conditions adversely affect the patient’s oral and/or systemic health. Consideration should be given to removal when there is a high probability of disease or pathology and/or the risks associated with early removal are less than the risks of later removal. Postoperative complications for removal of impacted third molars are low when performed at an early age. A Cochrane review in 2012 reported that there was no difference in late lower incisor crowding with removal or retention of asymptomatic impacted third molars.

Referral for regular and periodic dental care

As adolescent patients approach the age of majority, it is important to educate the patient and parent on the value of transitioning to a dentist who is knowledgeable in adult oral health care. At the time agreed upon by the patient, parent, and pediatric dentist, the patient should be referred to a specific practitioner in an environment sensitive to the adolescent’s individual needs. Until the new dental home is established, the patient should maintain a relationship with the current care provider and have access to emergency services. For the patient with special health care needs, in cases where it is not possible or desired to transition to another practitioner, the dental home can remain with the pediatric dentist and appropriate referrals for specialized dental care should be recommended when needed. Proper communication and records transfer allow for consistent and continuous care for the patient.

Recommendations by age

6 to 12 months

1. Complete the clinical oral examination with adjunctive diagnostic tools (e.g., radiographs as determined by child’s history, clinical findings, and susceptibility to oral disease) to assess oral growth and development, pathology, and/or injuries; provide diagnosis.

2. Complete a caries risk assessment.

3. Provide oral hygiene counseling for parents.

3. Clean and remove supragingival and subgingival stains or deposits as indicated.

4. Assess the child’s systemic and topical fluoride status (including type of infant formula used, if any, and exposure to fluoridated toothpaste) and provide counseling regarding fluoride.
Prescribe systemic fluoride supplements, if indicated, following assessment of total fluoride intake from drinking water, diet, and oral hygiene products.

5. Assess appropriateness of feeding practices, including bottle and breast-feeding, and provide counseling as indicated.

6. Provide dietary counseling related to oral health.

7. Provide age-appropriate injury prevention counseling for orofacial trauma.

8. Provide counseling for nonnutritive oral habits (e.g., digit, pacifiers).

9. Provide required treatment and/or appropriate referral for any oral diseases or injuries.

11. Assess overall growth and development and make appropriate referral to therapeutic services if needed.

12. Consult with the child’s physician as needed.

14. Determine the interval for periodic reevaluation based on the child’s individual needs or risk status/susceptibility to disease.

### 12 to 24 months

1. Repeat the procedures for ages six to 12 months every six months or as indicated by the child’s individual needs or risk status/susceptibility to disease.

2. Assess appropriateness of feeding practices (including bottle, breast-feeding, and no-spill training cups) and provide counseling as indicated.

3. Review patient’s fluoride status (including any childcare arrangements which may impact systemic fluoride intake) and provide parental counseling.

4. Provide topical fluoride treatments every six months or as indicated by the child’s individual needs or risk status/susceptibility to disease.

### 2 to 6 years

1. Repeat the procedures for 12 to 24 months every six months or as indicated by the child’s individual needs or risk status/susceptibility to disease. Provide age-appropriate oral hygiene instructions.

2. Scale and clean the teeth every six months or as indicated by individual patient’s needs.
3. Provide pit and fissure sealants for caries-susceptible primary molars and permanent molars, premolars, and anterior teeth.

4. Provide counseling and services (e.g., mouthguards) as needed for orofacial trauma prevention.

5. Provide assessment/treatment or referral of developing malocclusion as indicated by individual patient’s needs.

6. Provide required treatment and/or appropriate referral for any oral diseases, habits, or injuries as indicated.

7. Assess speech and language development and provide appropriate referral as indicated.

6 to 12 years

1. Repeat the procedures for ages two to six years every six months or as indicated by the child’s individual needs or risk status/susceptibility to disease.

2. Provide substance abuse counseling and/or referral to primary care providers or behavioral-health/addiction specialists if indicated (e.g., smoking, smokeless tobacco).

3. Provide counseling on intraoral/perioral piercing.

12 years and older

1. Repeat the procedures for ages six to 12 years every six months or as indicated by the child’s individual needs or risk status/susceptibility to disease.

2. During late adolescence, assess the presence, position, and development of third molars, giving consideration to removal when there is a high probability of disease or pathology and/or the risks associated with early removal are less than the risks of later removal.

3. At an age determined by patient, parent, and pediatric dentist, refer the patient to a general dentist for continuing oral care.

## Recommendations for Pediatric Oral Health Assessment, Preventive Services, and Anticipatory Guidance/Counseling

Since each child is unique, these recommendations are designed for the care of children who have no contributing medical conditions and are developing normally. These recommendations will need to be modified for children with special health care needs or if disease or trauma manifests variations from normal. The American Academy of Pediatric Dentistry (AAPD) emphasizes the importance of very early professional intervention and the continuity of care based on the individualized needs of the child. Refer to the text of this guideline for supporting information and references. Refer to the text in the Recommendations on the Periodicity of Examination, Preventive Dental Services, Anticipatory Guidance, and Oral Treatment for Infants, Children, and Adolescents (www.aapd.org/policies/) for supporting information and references.

</table>

1 First examination at the eruption of the first tooth and no later than 12 months. Repeat every 6 months or as indicated by child’s risk status/susceptibility to disease. Includes assessment of pathology and injuries.
2 By clinical examination.
3 Must be repeated regularly and to maximize effectiveness.
4 Timing, selection, and frequency determined by child’s history, clinical findings, and susceptibility to oral disease.
5 Consider when systemic fluoride exposure is suboptimal. Up to at least 16 years.
6 Appropriate discussion and counseling should be an integral part of each visit for care.
7 Initially, responsibility of parent; as child matures, jointly with parent; then, when indicated, only child.
8 At every appointment; initially discuss appropriate feeding practices, then the role of refined carbohydrates and frequency of snacking in caries development and childhood obesity.
9 Initially play objects, pacifiers, or car seats; when learning to walk; then with sports and routine playing, including the importance of mouthguards.
10 At first, discuss the need for additional sucking: digits vs pacifiers; then the need to wean from the habit before malocclusion or skeletal dysplasia occurs. For school-aged children and adolescent patients, counsel regarding any existing habits such as fingernail biting, clenching, or bruxism.
11 For caries-susceptible primary molars, permanent molars, premolars, and anterior teeth with deep pits and fissures; placed as soon as possible after eruption.
