Guideline on Oral Health Care for the Pregnant Adolescent

Originating Council
Council on Clinical Affairs, Committee on the Adolescent

Adopted
2007

Revised
2012

Purpose
The American Academy of Pediatric Dentistry (AAPD), as the oral health advocate for infants, children, adolescents, and persons with special needs, recognizes that adolescent pregnancy remains a significant social and health issue in the US. This guideline is intended to address management of oral health care particular to the pregnant adolescent rather than provide specific treatment recommendations for oral conditions.

Methods
This document is an update of the guideline adopted in 2007. The revision included an electronic search of the PubMed® database using the following parameters: Terms: "pregnancy", "adolescent pregnancy", "maternal", "pre-term birth", "oral health", "low birth weight delivery", and "periodontal disease"; Field: all fields; Limits: within the last 10 years, humans, English, clinical trials. The reviewers selected 79 articles that met the defined criteria to update this guideline. When data did not appear sufficient or were inconclusive, recommendations were based upon expert and/or consensus opinion by experienced researchers and clinicians.

Background
General considerations
In 2009, a total of 409,840 infants were born to 15-19 year olds, for a live birth rate of 39.1 per 1000 women in this age group.\(^1\) While the US teen birth rate fell by more than one-third from 1991 through 2005, it then increased by 5% over 2 consecutive years. Data for 2008 and 2009 indicate that the long-term downward trend has resumed.\(^2\) Approximately 50% of adolescent pregnancies occur within the first 6 months of initial sexual intercourse, even with increasing use of contraceptives by adolescents.\(^3\) The correlation between poverty and adolescent pregnancy is great, for as many as 83% of adolescent females who give birth are from low-income families.\(^4\) Once an adolescent has given birth to one child, she is at increased risk for giving birth to another child during adolescence.\(^5\) There exist racial, ethnic, and economic disparities related to oral hygiene practices and dental service utilization during pregnancy; reports indicate minority pregnant adolescents had only limited dental visits and possessed limited knowledge of oral health and pregnancy outcomes.\(^6,7\)

Medical complications involving mother and child occur more frequently in pregnant females aged 11 through 15 years than those aged 20 to 22 years.\(^8\) These include the delivery of low birth weight infants, increased neonatal death rate, and increased mortality rate for the mother.\(^8\) In addition, pregnancy-induced hypertension, anemia, sexually transmissible diseases, and premature delivery are concerns for the pregnant adolescent.\(^9\) Hypertension increases the risk of bleeding during procedures. Blood pressure \(\geq 140/90\) mmHg is considered mild hypertension, whereas values \(\geq 160/110\) mmHg are considered severe.\(^10\)

The diet of the pregnant adolescent can affect the health of the child. A healthy diet is necessary to provide adequate amounts of nutrients to the mother-to-be and the unborn child.\(^11\) Nutrients of particular importance include folate, vitamin B-6, vitamin B-12, calcium, and zinc.\(^12\) During pregnancy, a woman’s nutritional needs are increased, but certainly “the eating for 2” concept is not recommended.\(^13\) The total energy needs during pregnancy range between 2,500 to 2,700 kcal a day for most women, but pre-pregnancy body mass index, rate of weight gain, maternal age, and physiological appetite must be considered in tailoring this recommendation to the individual.\(^14\) Nausea and vomiting occur in 50 to 90 percent of all pregnancies during the first trimester and often are associated with young age and low socioeconomic status.\(^15\) An expectant female may modify food choices due to morning sickness and/or taste aversions, but appropriate nutrition for the health of the mother and fetus is crucial.

The goal of any drug therapy during pregnancy is to improve maternal/fetal health while avoiding adverse drug reactions.\(^16\) Reporting that medications for pregnant patients sometimes are prescribed under less than optimal conditions, a study of obstetrician-gynecologists emphasizes the importance of generating and having available to health care providers up-to-date information on effects of medications during pregnancy.\(^17\) The US Food and Drug
Oral conditions associated with pregnancy

Changes in the oral cavity have been associated with pregnancy. These include alterations in both the hard and soft tissues. An increase in caries has been associated with carbohydrate loading as snacking becomes more frequent. In some instances, morning sickness and vomiting/reflux may contribute to the onset of perimyolysis, an erosion of the lingual surfaces of the teeth caused by exposure to gastric acids. A confounding factor is that pregnancy-associated hormonal changes may cause dryness of the mouth. Approximately 44 percent of pregnant participants in one study reported persistent xerostomia.

From a periodontal perspective, the effects of hormonal levels on the gingival status of pregnant women may be accompanied by increased levels of Bacteroides, Prevotella, and Porphyromonas. Signs of gingivitis (e.g., bleeding, redness, swelling, tenderness) are evident in the second trimester and peak in the eighth month of pregnancy, with anterior teeth affected more than posterior teeth. These findings are exacerbated by poor plaque control and mouth breathing. Increased tooth mobility has been associated with microbial shifts from aerobic to anaerobic bacteria. These bacterial shifts are accompanied by increased inflammation in the attachment apparatus, as well as mineral disturbances in the lamina dura, causing tooth mobility. This condition appears to reverse postpartum.

The study of periodontitis during pregnancy and its effect on preterm, low birth weight infants is ongoing. Early studies noted an increase rate of preterm/low birthweight deliveries associated with periodontal disease. However, a more recent study of 116 postpartum women noted clinical attachment level measures were not different between those with preterm/low birthweight babies and control groups. Therefore, maternal periodontal microbiota and clinical characteristics of periodontal disease were not associated with having preterm/low birthweight babies.

More recent studies continue to demonstrate conflicting results. Several studies conducted in the US, including the Oral Conditions and Pregnancy (OCAP) Cohort Study, have shown an increased risk of adverse pregnancy outcome(s) with periodontal disease. The OCAP studies also showed increased odds of the adverse pregnancy outcomes of preeclampsia, fetal immune response, and very early preterm birth, among other conditions. The best available evidence to date shows that periodontal treatment has no effect on birth outcomes of preterm labor and low preterm birthweight and is safe for the mother and fetus. The effect of periodontitis and the development of preeclampsia, a rapidly progressing condition occurring in pregnancy characterized by hypertension and the presence of proteinuria, continues to be studied as well.

Oral health care during pregnancy
A multi-state study concluded that, besides neglecting medical care during pregnancy, most expectant females of all ages do not seek dental care, even though 50 percent of them have a dental problem. A woman’s lack of receiving routine dental care when not pregnant was the most significant predictor of lack of receiving care during pregnancy. The expectant mother might question the safety of dental treatment during pregnancy. Untreated oral disease may compromise the health of the pregnant female and the unborn child. The consequences of not treating an active infection during pregnancy outweigh the possible risks presented by most of the medications required for dental care.

In addition, deferring elective dental treatment during a healthy pregnancy is not justified. The amount of radiation exposure from dental x-rays is very small, ranging from 0.038 millisieverts (mSv) for bitewing radiographs to 0.15mSv for a full mouth series. During dental radiographic examination of a pregnant patient, optimizing techniques, shielding the thyroid and abdomen, choosing the fastest available image receptor (ie, high-speed film, rare earth screen-film systems, digital radiography), and avoiding retakes help minimize radiation exposure to the fetus. The health care provider must be aware that the primary dental x-ray beam may pass near or through the thyroid gland, even with attention to proper radiographic techniques. The juvenile thyroid is among the most sensitive organs to radiation-induced tumors, both benign and malignant. Risk decreases significantly with age at exposure, essentially disappearing after age 20. Evidence shows that radiation exposure to the thyroid during pregnancy is associated with low birthweight. Common dental projections rarely, if ever, deliver a measurable absorbed dose to the embryo or fetus. Gonadal absorbed dose from a typical dental x-ray procedure is equivalent to about 1 hour of natural background radiation. The National Council on Radiation Protection and Measurements recommends if dental treatment is to be deferred until after the delivery, so should the dental radiographs.

The objectives of professional oral health care during the first trimester include avoiding fetal hypoxia, premature labor/fetal demise, and teratogenic effects. Due to the increased risk of pregnancy loss, use of nitrous oxide may be contraindicated in the first trimester of pregnancy. Prevention, diagnosis, and treatment of oral diseases (including needed dental x-rays and use of local anesthesia) are highly beneficial and can be undertaken any time during pregnancy with no additional fetal or maternal risk as compared to not providing care. It is safe to provide dental treatment throughout pregnancy; however, because the pregnant uterus is below the umbilicus, the woman is generally more comfortable during weeks 14 to 20 of gestation. Pregnant women are considered to have a “full stomach” due to delayed gastric emptying and, therefore, are at increased risk for aspiration, particularly during the last trimester. Elective restorative and periodontal therapies during the second trimester may prevent any dental infections or other complications from occurring in the third trimester. In the final trimester, a dental prophylaxis may be repeated, especially if home oral care is inadequate or if soft tissue is abnormal.

Evidence is insufficient to support or refute that mercury exposure from dental amalgams contributes to adverse pregnancy outcomes. Currently, there is no evidence that the exposure of a fetus to mercury releases from the mother’s existing amalgam fillings causes any adverse effects. Mercury vapor released during the removal or placement of amalgam restorations may be inhaled and absorbed into the blood stream and does cross the placental barrier. The use of rubber dam and high speed suction can reduce the risk of vapor inhalation. Because use of tooth whitening products that contain or generate hydrogen peroxide results in release of inorganic mercury from dental amalgams, these products should be avoided during pregnancy by patients having amalgam restorations.

Suppression of the mother’s reservoirs of Mutans streptococci (MS) by dental rehabilitation and antimicrobial treatments may prevent or at least delay infant acquisition of these cariogenic microorganisms. MS, present in children with early childhood caries, is predominantly acquired from mother’s saliva. MS generally is considered to be a principal group of bacterial organisms responsible for the initiation of dental caries. MS colonization of an infant may occur from the time of birth. Improving oral health during pregnancy leads to a reduction in salivary MS in the offspring. Beginning in the sixth month of pregnancy, a daily rinse of 0.05 percent sodium fluoride and 0.12 percent chlorhexidine has resulted in significant reduction in levels of caries-causing bacteria, consequently delaying the colonization of such bacteria among offspring. Xylitol, a naturally occurring sweetener, has been added to a variety of products because of its potential to reduce caries incidence. Evidence suggests maternal use of xylitol chewing gum (at least 2-3 times a day) has a significant impact on mother-child transmission of MS and subsequent decrease of the child’s caries rate.

Education is an important component of prenatal oral health care and may have a significant effect on the oral health of both the mother and the child. Counseling for the pregnant adolescent includes topics directed toward all adolescent patients (eg, dietary habits, injury prevention, third molars), as well as oral changes that may occur during pregnancy and infant oral health care. Since the pregnant adolescent may be receptive to information that will improve the infant’s health, anticipatory guidance, a proactive developmentally-based counseling technique, can be introduced to focus on the needs of the child at each stage of life. Studies have documented that early oral health care promotion starting during pregnancy can lead to a sustained and long-term improvement of the oral health of children.
Legal considerations
Statutes and case law concerning consent involving pregnant patients less than 18 years of age vary from state to state. In some states, dentists are required to obtain parental consent for non-emergency dental services provided to a child 17 years of age or younger who remains under parental care.72 This would involve obtaining consent from the parent who must be aware of the pregnancy in order to understand the risks and benefits of the proposed dental treatment.66 However, if the parent is unaware of the pregnancy, the pregnant adolescent may be entitled to confidentiality regarding health issues such as the pregnancy.73 In other states, there are “mature minor” laws that allow minors to consent for their own health care when a dentist deems the minor competent to provide informed consent. In addition, some states emancipate minors who are pregnant or by court order. Practitioners are obligated to be familiar with and abide by the laws specific to where they practice and where the patient resides.

Recommendations
The AAPD recommends that all pregnant adolescents seek professional oral health care during the first trimester. After obtaining a thorough medical history, the dental professional should perform a comprehensive evaluation which includes a thorough dental history, dietary history, clinical examination, and caries risk assessment. The dental history includes, but is not limited to, discussion of preexisting oral conditions, signs/symptoms of such, current oral hygiene practices and preventive home care, previous radiographic exposures, and tobacco use.20-25 The adolescent’s dietary history should focus on exposures to carbohydrates, especially due to increased snacking, and acidic beverages/foods. During the clinical examination, the practitioner should pay particular attention to health status of the periodontal tissues.27,28 The AAPD’s caries-risk assessment guideline74, utilizing historical and clinical findings, will aid the practitioner in identifying risk factors in order to develop an individualized preventive program.

Based upon the historical indicators, clinical findings, and previous radiographic surveys, radiographs may be indicated. However, if the parent is unaware of the pregnancy, the pregnant adolescent may be entitled to confidentiality regarding health issues such as the pregnancy.73 In other states, there are “mature minor” laws that allow minors to consent for their own health care when a dentist deems the minor competent to provide informed consent. In addition, some states emancipate minors who are pregnant or by court order. Practitioners are obligated to be familiar with and abide by the laws specific to where they practice and where the patient resides.
treatment for a pregnant patient who is experiencing pain or infection should not be delayed until after delivery. When selecting therapeutic agents for local anesthesia, infection, postoperative pain, or sedation, the dentist must evaluate the potential benefits of the dental therapy versus the risk to the pregnant patient and the fetus. The practitioner should select the safest medication, limit the duration of the drug regimen, and minimize dosage. Health care providers should avoid the use of aspirin, aspirin-containing products, erythromycin estolate, and tetracycline in the pregnant patient. Non-steroidal anti-inflammatory drugs routinely are not recommended during pregnancy; if necessary, administration should be avoided during the first and third trimesters and be limited to 48-72 hours.

Patients requiring restorative care should be counseled regarding the risk and benefits and alternatives to amalgam fillings. The dental practitioner should use rubber dam and high speed suction during the placement or removal of amalgam to reduce the risk of vapor inhalation. Consultation with the prenatal medical provider should precede use of nitrous oxide/oxygen analgesia/anxiolysis during pregnancy. Nitrous oxide inhalation should be limited to cases where topical and local anesthetics alone are inadequate. Precautions must be taken to prevent hypoxia, hypotension, and aspiration.

The pediatric dentist should incorporate positive youth development (PYD) into care for the adolescent patient. This approach goes beyond traditional prevention, intervention, and treatment of risky behaviors and problems and suggests that a strong interpersonal relationship between the adolescent and the pediatric dentist can be influential in improving adolescent oral health and transitioning to adult care. Through PYD, the dentist can promote healthy lifestyles, teach positive patterns of social interaction, and provide a safety net in times of need. At a time agreed upon by the patient, parent, and pediatric dentist, the patient should be transitioned to a practitioner knowledgeable and comfortable with managing that patient’s specific oral care needs.

Dental practitioners must be familiar with state statutes that govern consent for care for a pregnant patient less than the age of majority. If a pregnant adolescent’s parents are unaware of the pregnancy, and state laws require parental consent for dental treatment, the practitioner should encourage the adolescent to inform them so appropriate informed consent for dental treatment can occur.
