Prescribing Dental Radiographs for Infants, Children, Adolescents, and Individuals with Special Health Care Needs

Latest Revision
2021

ABBREVIATIONS

Purpose
The American Academy of Pediatric Dentistry (AAPD) intends these recommendations to help practitioners make clinical decisions concerning appropriate selection of dental radiographs as part of an oral evaluation of infants, children, adolescents, and individuals with special health care needs. The recommendations can be used to optimize patient care, minimize radiation burden, and allocate health care resources responsibly.

Methods
In 1981, the Ad Hoc Committee on Pedodontic Radiology of the American Academy of Pedodontics developed guidance on radiographic examination of pediatric dental patients. Six years later, the U.S. Food and Drug Administration (FDA) published recommendations developed by an expert dental panel, which included a representative of the AAPD, convened “to reach a consensus on standardizing dental radiographic procedures.” In 2002, the American Dental Association (ADA) initiated a review of that document. The AAPD, along with other dental specialty organizations, participated in the review and revision of those guidelines. The FDA accepted the revision in November 2004, and the AAPD endorsed it the following spring. The ADA Council on Scientific Affairs has published updates to their recommendations for dental radiographs. While continuing to endorse the ADA/FDA’s recommendations, the AAPD expanded its guidance on dental radiographs, with the last revision in 2017. This review includes a new search of the PubMed®/MEDLINE database using the terms: dental radiology, dental radiographs, dental radiography, cone-beam computed tomography AND guidelines, recommendations; fields: all; limits: within the last 10 years, humans, and English.

Background
Radiographs are valuable aids in the oral health care of infants, children, adolescents, and individuals with special health care needs. They are used to diagnose and monitor oral diseases, evaluate dentoalveolar trauma, as well as monitor dentofacial development and the progress of therapy. The recommendations in the ADA/FDA guidelines were developed to serve as an adjunct to the dentist’s professional judgment. The timing of the initial radiographic examination should not be based upon the patient’s age, but upon each child’s individual circumstances. Radiographic screening for the purpose of detecting disease before clinical examination should not be performed. Each patient is unique, the need for dental radiographs can be determined only after consideration of the patient’s medical and dental histories, completion of a thorough clinical examination, and assessment of the patient’s vulnerability to environmental factors that affect oral health. AAPD’s recommendations for assessing risk for caries development in children ages 0-5 years and ≥6 years can be found in Caries-risk Assessment and Management for Infants, Children, and Adolescents. Review of prior radiographs, when available from within the same practice or through record transfer, also contributes to the decision of radiographic necessity. Radiographs should be taken to substantiate a clinical diagnosis and guide the practitioner in making an informed decision that will affect patient care. The AAPD recognizes that there may be clinical circumstances for which a radiograph is indicated, but a diagnostic image cannot be obtained. When diagnostic radiographs cannot be obtained due to a lack of cooperation, technical issues, or a health care facility lacking in intraoral radiographic capabilities, the practitioner should inform the patient or guardian of these limitations and document these discussions in the patient’s record. The decision to treat the patient without radiographs will depend upon the urgency of the treatment needs, availability and appropriateness of alternative treatment settings, and relative risks and benefits of the various
treatment options for the patient. Because the effects of radiation exposure accumulate over time,4,9 every effort must be made to minimize the patient’s exposure. Good radiological practices are important in minimizing or eliminating unnecessary radiation in diagnostic dental imaging. Examples of good radiologic practice include: 1) use of the fastest image receptor compatible with the diagnostic task (F-speed film or digital [photostimulable phosphor (PSP) plate, charge-coupled device (CCD)]), 2) collimation of the beam to the size of the receptor whenever feasible,10-12 3) proper film exposure and processing techniques, 4) use of protective aprons and thyroid collars, and 5) limiting the number of images to the minimum necessary to obtain essential diagnostic information.6 The dentist must weigh the benefits of obtaining radiographs against the patient’s risk of radiation exposure. Some of the newer panoramic machines are capable of producing extraoral bitewings. The radiation dose is similar to a traditional panoramic radiograph, although it is 3-11 times more than the traditional intraoral bitewing.13 Therefore, the extraoral bitewing should be prescribed based upon case specific needs and not as an alternative to intraoral radiographs.14

New imaging technology (i.e., cone beam computed tomography [CBCT]) has added three-dimensional capabilities that have many applications in dentistry. The use of CBCT has been valuable as an adjunct diagnostic tool in assessing periapical pathosis in endodontics, oral pathology, anomalies in the developing dentition (e.g., impacted, ectopic, or super numerary teeth), oral maxillofacial surgery (e.g., cleft palate), dental and facial trauma, and orthodontic and surgical preparation for orthognathic surgery. For all procedures using CBCT, the clinical benefits must be balanced against the potential risks. Considering the cumulative effect of ionizing radiation4,9, and that children are more prone to radiation induced carcinogenesis than an adult, the clinician needs to be aware of the inherent risks associated with cone beam tomography and the as low as reasonably achievable (ALARA) principle in patient selection.15 The American Academy of Oral and Maxillofacial Radiology (AAOMR) has published position statements which summarize the potential benefits and risks of maxillofacial CBCT use in orthodontic and endodontic diagnosis, treatment, and outcomes and provides clinical guidance to dental practitioners.16,17 The AAOMR’s position statements support and affirm the position of the ADA Council on Scientific Affairs that the selection of CBCT imaging must be justified based on individual need.16-18 Because this technology has potential to produce vast amounts of data and imaging information beyond initial intentions, it is important to interpret all information obtained, including that which may be beyond the immediate diagnostic needs or abilities of the practitioner, and CBCT imaging should be referred for radiological and diagnostic interpretation.

Recommendations
The recommendations of the ADA/FDA guidelines are contained within the accompanying Table. “These recommendations are subject to clinical judgment and may not apply to every patient. They are to be used by dentists only after reviewing the patient’s health history and completing a clinical examination. Even though radiation exposure from dental radiographs is low, once a decision to obtain radiographs is made, it is the dentist’s responsibility to follow the as low as reasonably achievable (ALARA principle) to minimize the patient’s exposure.”6

Intraoral imaging should be maintained as the standard diagnostic tool. The use of CBCT should be considered when conventional radiographs are inadequate to complete diagnosis and treatment planning and the potential benefits outweigh the risk of additional radiation dose. It must not be routinely prescribed for diagnosis or screening purposes in the absence of clinical indication. Basic principles and guidelines for the use of CBCT include: 1) use appropriate image size or field of view, 2) assess the radiation dose risk, 3) minimize patient radiation exposure and, 4) maintain professional competency in performing and interpreting CBCT studies.16-19 When using CBCT, the resulting imaging is required to be supplemented with a written report placed in the patient’s records that includes full interpretation of the findings.

</table>
* Clinical situations for which radiographs may be indicated include, but are not limited to:

**A. Positive Historical Findings**
1. Previous periodontal or endodontic treatment
2. History of pain or trauma
3. Familial history of dental anomalies
4. Postoperative evaluation of healing
5. Remineralization monitoring
6. Presence of implants, previous implant-related pathosis or evaluation for implant placement

**B. Positive Clinical Signs/Symptoms**
1. Clinical evidence of periodontal disease
2. Large or deep restorations
3. Deep carious lesions
4. Malposed or clinically impacted teeth
5. Swelling
6. Evidence of dental/facial trauma
7. Mobility of teeth
8. Sinus tract ("fistula")
9. Clinically suspected sinus pathosis
10. Growth abnormalities
11. Oral involvement in known or suspected systemic disease
12. Positive neurologic findings in the head and neck
13. Evidence of foreign objects
14. Pain and/or dysfunction of the temporomandibular joint
15. Facial asymmetry
16. Abutment teeth for fixed or removable partial prosthesis
17. Unexplained bleeding
18. Unexplained sensitivity of teeth
19. Unusual eruption, spacing or migration of teeth
20. Unusual tooth morphology, calcification or color
21. Unexplained absence of teeth
22. Clinical tooth erosion
23. Peri-implantitis

**Factors increasing risk for caries may be assessed using the ADA Caries Risk Assessment forms (0–6 years of age<sup>20</sup> and over 6 years of age<sup>21</sup>).**
