Policy on Early Childhood Caries (ECC): Consequences and Preventive Strategies

Latest Revision
2021

Purpose
Early childhood caries (ECC), formerly referred to as nursing bottle caries and baby bottle tooth decay, remains a significant chronic disease of childhood and public health problem.¹ The American Academy of Pediatric Dentistry (AAPD) encourages healthcare providers and caregivers to implement preventive practices that can decrease a child’s risks of developing this preventable disease to reduce the burden on the child, the family, and society.

Methods
This policy was developed in a collaborative effort of the American Academy of Pedodontics and the American Academy of Pediatrics (AAP) and adopted in 1978.² This document is a revision of the previous version, last revised by the AAPD in 2016.³ The update used electronic and hand searches of English written articles in the dental and medical literature within the last 14 years, using the search terms infant oral health, infant oral health care, early childhood caries, early childhood caries AND oral microbiome, ECC AND oral microbiome, early childhood caries AND prevention, ECC AND prevention. More than 8000 articles were identified in the search. When information from these articles did not appear sufficient or was inconclusive, policies were based upon expert and consensus opinion by experienced researchers and clinicians.

Background
In 1978, the American Academy of Pedodontics and the AAP released a joint statement Nursing Bottle Caries to address a severe form of caries associated with bottle usage.⁴ Initial policy recommendations were limited to feeding habits, concluding that nursing bottle caries could be avoided if bottle feedings were discontinued soon after the first birthday. An early policy revision added ad libitum breastfeeding as a causative factor. Over the next two decades, however, recognizing that ECC was not solely associated with poor feeding practices, AAPD adopted the term ECC to better reflect its multifactorial etiology. These factors include susceptible teeth due to enamel hypoplasia, oral colonization with elevated levels of cariogenic bacteria (especially Mutans streptococci [MS]), and the metabolism of sugars by tooth-adherent bacteria to produce acid which, over time, demineralizes tooth structure.⁵

ECC is defined as “the presence of one or more decayed (noncavitated or cavitated lesions), missing (due to caries), or filled tooth surfaces in any primary tooth”⁶ in a child under the age of six. The definition of severe early childhood caries (S-ECC) is 1) any sign of smooth-surface caries in a child younger than three years of age, 2) from ages three through five, one or more cavitated, missing (due to caries), or filled smooth surfaces in primary maxillary anterior teeth, or 3) a decayed, missing, or filled score of greater than or equal to four (age three), greater than or equal to five (age four), or greater than or equal to six (age five).⁷

Epidemiologic data from a 2011-2012 national survey clearly indicate that ECC remains highly prevalent in poor and near-poor United States (U.S.) preschool children.⁸ For the overall population of preschool children, the prevalence of ECC, as measured by decayed and filled tooth surfaces (dfs), is unchanged from previous surveys, but the filled component (fs) has greatly increased indicating that more treatment is being provided.⁹ The consequences of ECC often include a higher risk of new caries lesions in both the primary and permanent dentitions⁸,¹⁰, hospitalizations and emergency room visits⁸,¹⁰, high treatment costs¹¹, loss of school days¹², diminished ability to learn¹³, and diminished oral health-related quality of life¹⁴.

Traditional microbial risk markers for ECC include acidogenic-aciduric bacterial species, namely MS and Lactobacillus species.¹⁵ Studies using direct culture with arbitrarily primed polymerase chain reaction (AP-PCR) fingerprinting and other traditional techniques have shown that MS maybe transmitted vertically from parent or caregiver to child and horizontally from other individuals in his immediate environment.¹⁶,¹⁷ Newer technologies that sequence DNA and RNA in a rapid and cost-effective manner, known as high-throughput or new-generation sequencing (e.g. polymerase chain reaction, rRNA gene sequencing), reveal the complexity of the oral microbiome and have highlighted other bacterial species (e.g., Scardovia wiggsiae, Veillonella spp.) and fungi (e.g., Candida albicans).

ABBREVIATIONS
that also may be associated with ECC. Recent studies on the development of the oral microbiome since birth continue to support the concept of vertical and horizontal transmission as well as the importance of diet and environmental exposures. Parental education and counseling on the importance of a healthy microbiome and diet in infancy should be conducted as early as possible.

An associated risk factor to microbial etiology is high consumption of sugars. Nighttime bottle feeding with juice, repeated use of a sippy or no-spill cup, and frequent in-between meal consumption of sugar-added snacks or drinks (e.g., juice, formula, soda) increase the risk of caries. Although there are clear benefits of breastfeeding in a child’s first year of life, breastfeeding and baby bottle use beyond 12 months, especially if frequent and/or nocturnal, are associated with ECC. The American Heart Association recommends that sugar in foods and drink should be avoided in children under two years of age. Additionally, the American Academy of Pediatrics recommends that 100 percent fruit a day for children between the ages of one and three.

Community water fluoridation (CWF) as a primary prevention method is considered a key strategy for preventing dental caries. Children with lifetime exposure to CWF show significantly lower dental caries levels than those without, with the benefit being most pronounced in primary teeth. In addition to reducing the prevalence of severe caries, the use of CWF in high-risk populations may reduce caries-related visits and help avoid preventable dental surgery under general anesthesia. CWF has multiple benefits and attenuates income-related inequalities in dental caries in the U.S. Apart from an increased incidence of enamel fluorosis, the literature fails to provide credible evidence linking CWF with negative health outcome.

Current best practice to reduce the risk of ECC includes twice-daily brushing with fluoridated toothpaste for all children in optimally-fluoridated and fluoride-deficient communities. When determining the risk-benefit of fluoride, the key issue is mild fluorosis versus preventing dental disease. A smear or rice-sized amount of fluoridated toothpaste (approximately 0.1 milligram [mg] fluoride; see Figure) should be used for children younger than three years of age. A pea-sized amount of fluoridated toothpaste (approximately 0.25 mg fluoride) is appropriate for children aged three to six. Parents should dispense the toothpaste onto a soft, age-appropriate sized toothbrush and perform or assist with toothbrushing of preschool-aged children. To maximize the beneficial effect of fluoride in the toothpaste, rinsing after brushing should be kept to a minimum or eliminated altogether. Less than twice daily tooth-brushing and difficulties in performing the procedure during the preschool years were significant determinants of caries prevalence at the age of five years.

Professionally-applied topical fluoride treatments also are efficacious in reducing prevalence of ECC. The recommended professionally-applied fluoride treatment for children at risk for ECC who are younger than six years is five percent sodium fluoride varnish (NaFV; 22,500 parts per million F). Additionally, the use of 38 percent silver diamine fluoride (SDF) is effective for the arrest of cavitated caries lesions in primary teeth. Evidence suggests that preventive interventions within the first year of life are critical. For this reason, establishment of a dental home within six months of the eruption of the first tooth and no later than 12 months of age is especially important in populations at risk. This may be best implemented with the help of medical providers who, in many cases, are being trained to provide oral screenings, apply preventive measures, counsel caregivers, and refer infants and toddlers for dental care.

**Policy statement**

The AAPD recognizes early childhood caries as a significant chronic disease resulting from an imbalance of multiple risk and protective factors over time. To decrease the risk of developing ECC, the AAPD encourages professional and at-home preventive measures that provide evidence-based prevention of ECC such as:

1. establishing a dental home within six months of eruption of the first tooth and no later than 12 months of age to conduct caries risk assessment, parental education, and anticipatory guidance.
2. modifying diets to avoid frequent consumption of liquids and/or solid foods containing sugar, and
   - eliminating baby bottle- and breastfeeding beyond 12 months, especially if frequent or nocturnal.
   - encouraging children between six and 12 months old to drink four to six ounces of water per day.
   - avoiding sugar in foods and drink in children under two years of age.
   - abstaining from 100 percent fruit juice before 12 months of age.
   - limiting juice to no more than four ounces a day for children between the ages of one and three.
3. implementing early oral hygiene measures no later than the time of eruption of the first primary tooth. Toothbrushing should be performed for children by a parent twice daily, using a soft toothbrush of age-appropriate size. In children under the age of three years, a smear or rice-sized amount of fluoridated toothpaste should be used. In children ages three to six years, a pea-sized amount of fluoridated toothpaste should be used.
4. providing professionally-applied fluoride varnish treatments for children at risk for ECC.
5. supporting CWF as a primary prevention for dental caries to reach underserved and vulnerable communities.
6. working with medical providers to ensure all infants and toddlers have access to dental screenings, counseling, and preventive procedures with a consistent unified message.
7. educating legislators, policy makers, and third-party payors regarding the consequences of and preventive strategies for ECC, emphasizing the importance of access to care for all.
8. raising awareness of ECC with parents and oral health and medical professionals.
9. advocating for reimbursement systems to allow access for all children and educational reforms that emphasize evidence-based preventive and comprehensive management of ECC.
