Policy on Interim Therapeutic Restorations (ITR)

Latest Revision
2022

Purpose
The American Academy of Pediatric Dentistry (AAPD) recognizes that unique clinical circumstances can result in challenges in restorative care for infants, children, adolescents, and persons with special health care needs. When circumstances do not permit traditional cavity preparation and/or placement of traditional dental restorations, interim therapeutic restorations (ITR) may be beneficial and are best utilized as part of comprehensive care in the dental home. This policy will differentiate ITR from atraumatic/alternative restorative techniques (ART) and describe the circumstances for its use.

Methods
This policy was developed by the Council on Clinical Affairs, adopted in 2001, and revised in 2017. This update is based upon electronic database and hand searches of medical and dental literature using PubMed®/MEDLINE and the terms: dental caries, cavity, primary teeth, deciduous teeth, alternative restorative treatment, interim therapeutic restoration, AND glass ionomer; fields: all; limits: within the last 10 years, humans, English, birth through age 18. Two hundred ninety-one articles met these criteria. Articles were screened by viewing titles and abstracts. Articles were chosen for review from these searches and from the references within selected articles. Additionally, websites for the AAPD and the American Dental Association were reviewed. Expert and/or consensus opinion by experienced researchers and clinicians was also considered.

Background
ART has been endorsed by the World Health Organization as a means of restoring and preventing caries in populations with little access to traditional dental care. In many countries, practitioners provide treatment in nontraditional settings that restrict restorative care to placement of provisional restorations. Because circumstances do not allow for follow-up care, ART mistakenly has been interpreted as a definitive restoration. ITR utilizes similar techniques but has different therapeutic goals. Interim therapeutic restoration more accurately describes the procedure used in contemporary dental practice in the United States.

ITR may be used to restore, arrest, or prevent the progression of caries lesions in young patients, uncooperative patients, or patients with special health care needs or when traditional cavity preparation and/or placement of traditional dental restorations are not feasible and need to be postponed. Additionally, ITR may serve useful for stepwise excavation in children with multiple open caries lesions prior to definitive restoration of the teeth, in erupting molars when isolation conditions are not optimal for a definitive restoration, or for caries control in patients with active lesions prior to treatment performed under general anesthesia. ITR may be beneficial for patients who require additional acclimatization or increased cooperation to complete definitive restorative treatment. The use of ITR has been shown to reduce the levels of cariogenic oral bacteria (e.g., Mutans streptococci, lactobacilli) in the oral cavity immediately following its placement. However, this level may return to pretreatment counts over a period of six months after ITR placement if no other treatment is provided. ITR also may help reduce the risk of decay in teeth adjacent to the interim restoration. This technique serves as a viable tool when circumstances (e.g., coronavirus disease 2019 [COVID-19] pandemic) call for minimizing the generation of aerosols during restorative care.

The ITR procedure involves removal of caries using hand or rotary instruments with caution not to expose the pulp. Leakage of the restoration can be minimized with maximum caries removal from the periphery of the lesion. Following preparation, the tooth is restored with an adhesive restorative material such as glass ionomer or resin-modified glass ionomer cement. ITR has the greatest success when applied to single surface or small two surface restorations. Inadequate cavity preparation with subsequent lack of retention and insufficient bulk can lead to failure. Follow-up care with topical fluorides and oral hygiene instruction may improve the treatment outcome in high caries-risk dental populations, especially when glass ionomers (which have fluoride releasing and recharging properties) are used.

Policy statement
The AAPD recognizes ITR as a beneficial provisional technique in contemporary pediatric restorative dentistry. The AAPD supports the use of ITR to restore and prevent the

ABBREVIATIONS
progression of dental caries in young patients, uncooperative patients, patients with special health care needs, and situations in which traditional cavity preparation or placement of traditional dental restorations is not feasible. Furthermore, ITR may be used for caries control in children with multiple caries lesions prior to definitive restoration of the teeth.
